OverviewHistoryElectrochemistryMeasuring the charge levelVoltages for common usageConstructionApplicationsCyclesThe lead-acid battery is a type of rechargeable battery. First invented in 1859 by French physicist Gaston Planté, it was the first type of rechargeable battery ever created. Compared to the more modern rechargeable batteries, lead-acid batteries have relatively low energy density and heavier weight. Despite this, they are able to supply high surge currents. These features, along with their low cost, make them suitable for various applications, particularly in off-grid power systems and as backup power sources. The lead-acid battery consists of a series of cells, each containing a positive plate made of lead dioxide (PbO₂) and a negative plate made of lead (Pb). The plates are immersed in a sulfuric acid (H₂SO₄) electrolyte. During discharge, the lead dioxide is reduced to lead sulfate (PbSO₄), and the lead is oxidized to lead sulfate. The resulting lead sulfate is insoluble and forms a porous grid that allows for the movement of ions. This process releases energy, which is stored in the chemical bonds of the lead sulfate. During charging, the lead sulfate is reduced back to lead and lead dioxide, and the sulfuric acid is restored to its original state. The lead-acid battery is a reliable and cost-effective energy storage solution, but it has a relatively short lifespan and requires regular maintenance to prevent sulfation and ensure optimal performance.
